

## **SCHEDE SPECIFICHE PER TUMORE**

CANCER-SPECIFIC DATA SHEET

## 4 GUIDA ALLA LETTURA DELLE SCHEDE

### A GUIDE TO THE CANCER-SPECIFIC DATA SHEETS

Questa guida è indirizzata prevalentemente ai lettori non tecnici. L'obiettivo principale è di fornire gli strumenti interpretativi indispensabili per la lettura dei singoli indicatori: informazioni più dettagliate sono disponibili nel capitolo «Materiali e metodi» (pp. 205-26).

Le misure di sopravvivenza fornite possono essere lette:

- dal punto di vista generale, come la proporzione di pazienti che non sono deceduti a causa della malattia in studio, dopo un intervallo di tempo definito;
- dal punto di vista individuale, come la probabilità di sopravvivere alla malattia per un intervallo di tempo.

La misura più semplice a nostra disposizione è la sopravvivenza osservata, espressa genericamente come proporzione di pazienti viventi, dopo un intervallo di tempo definito, sul totale dei pazienti considerati. In questo caso, tutti i decessi avvenuti nell'intervallo (sia quelli dovuti alla patologia in studio, sia quelli dovuti ad altre cause) contribuiscono al calcolo dell'indicatore.

#### LIMITI INTERPRETATIVI DELLA SOPRAVVIVENZA OSSERVATA

Naturalmente i pazienti con tumore sono esposti al rischio di morire per questa malattia, ma anche per tutte le altre cause che interessano la popolazione non affetta da tumore; come effetto immediato si ha, per esempio, che la sopravvivenza osservata dei pazienti anziani, se confrontata con quella di pazienti più giovani, risulta più bassa verosimilmente per effetto della maggiore mortalità per altre cause. Ne consegue che la sopravvivenza osservata non possa essere utilizzata per effettuare confronti dell'impatto di una specifica malattia tra popolazioni diverse.

E', quindi, necessario utilizzare indicatori che tengano conto del fatto che un paziente possa morire come conseguenza della malattia in studio o, eventualmente, per altre cause, dette appunto "cause competitive".

Esistono due approcci che permettono di tener conto della presenza delle cause competitive di morte:

*This guide is for laymen. The main objective is providing basic knowledge for reading the indicators: for more detailed information please refer to the «Materials and methods» chapter (pp. 205-26).*

*The survival indicators may be interpreted:*

- *from a general prospective (population based), as the proportion of patients alive within a certain time interval;*
- *from the patient's point of view, as the probability of surviving the disease for a specific amount of time.*

*The simplest measure is observed survival, generally expressed as a proportion of patients alive after a defined time interval divided by the total number of treated patients. In this case, all deaths which occurred in the interval (both due to the disease under study or to other causes) contribute to the indicator's computation.*

#### INTERPRETATIVE CAUTIONS OF OBSERVED SURVIVAL

*Of course, the cancer patients are at risk of dying from this disease, but also from all other causes that affect the population free of the specific cancer under study.*

*It follows that observed survival cannot be used to make comparisons of the impact of a specific disease among different populations. In particular, observed survival is necessarily lower among older patients than among younger patients due partly to the effect of higher mortality for other causes among elderly subjects. It follows that a more appropriate measure should take into account only deaths attributable to the cancer under study, excluding non-cancer deaths, known as death for "competing causes".*

*Two approaches for taking account of competing causes of death are available:*

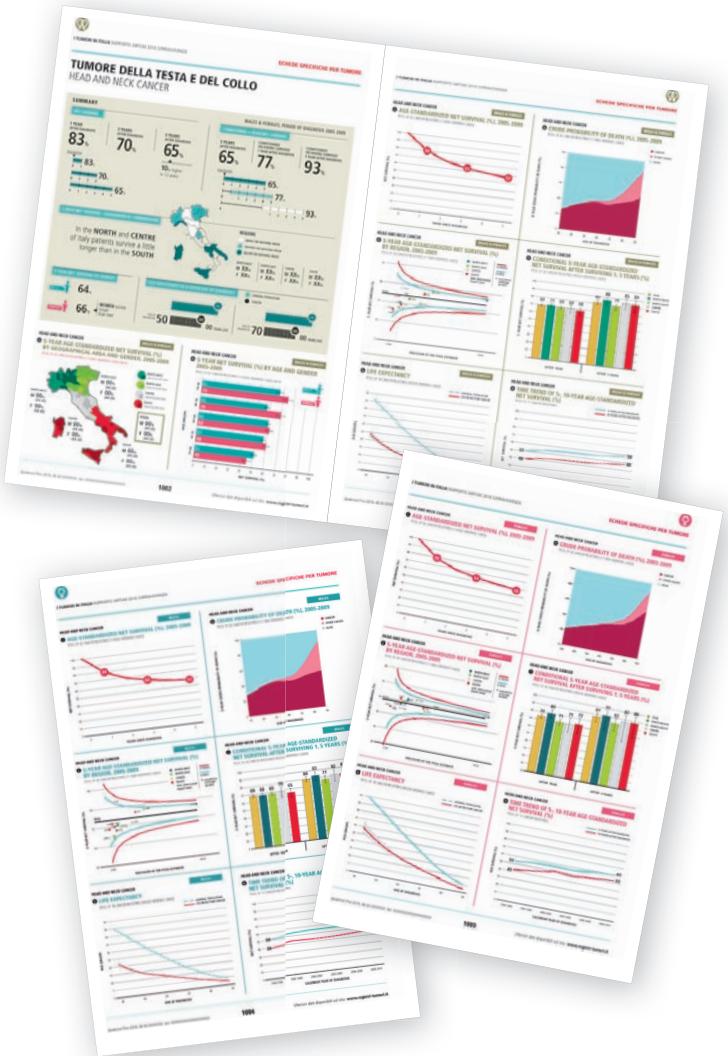

- *the first one is based on the analysis of a hypothetical (imaginary) situation where the disease under study is the only cause of death and leading to **net survival** estimation;*
- *the second one is based on the quantification of both the actual probability of dying from the disease under study and the*

■ il primo consiste nel ricondursi alla ipotetica (fittizia) situazione in cui la patologia in studio sia l'unica causa di morte e conduce alla stima della **sopravvivenza netta**;

■ il secondo consiste nel quantificare sia la probabilità effettiva di morte per la patologia in studio, sia la probabilità effettiva di morte per cause competitive: questo approccio è definito stima della **sopravvivenza reale** (in inglese *crude*). La sopravvivenza netta esprime la probabilità di sopravvivere dopo una diagnosi di tumore eliminando la distorsione derivante dalla possibilità di morire per altre cause. Questo indicatore è una stima ideale se lo scopo è quello di confrontare la sopravvivenza dopo una diagnosi di tumore tra popolazioni o periodi temporali diversi, poiché esclude che le differenze eventualmente riscontrate possano essere attribuite a variazioni del rischio di morire per cause diverse dal cancro; è, quindi, estremamente rilevante dal punto di vista della sanità pubblica.

**NOTA BENE.** Nel Rapporto AIRTUM 2011 la sopravvivenza netta era stata stimata attraverso la sopravvivenza relativa. In questo volume è stato utilizzato invece l'approccio di Pohar-Perme, che stima appunto la sopravvivenza netta. Nei grafici è riportata la sola dizione *Net survival* – sopravvivenza netta. La scelta di utilizzare questo nuovo indicatore è stata effettuata perché il metodo di Pohar Perme è robusto rispetto a violazioni dell'assunzione di indipendenza tra il rischio di morire per il cancro e il rischio di morire per altre cause.

L'approccio della stima della probabilità reale (in inglese *crude probability*) di morte permette di quantificare la probabilità di morire a causa del tumore, la probabilità di morire per altre cause e la probabilità di sopravvivere in un intervallo di tempo definito. Questo indicatore fornisce informazioni fruibili sia dal punto di vista dei pazienti e sia dei clinici, che possono essere interessati a conoscere la le probabilità effettive di sopravvivere e di morire, sia nella quota attribuibile al cancro sia nella quota attribuibile ad altre cause.

*actual probability of death for competing risks: this approach is known as **crude probability** estimation).*

*Net survival represents the probability of surviving after a cancer diagnosis, by eliminating the distortion arising from the possibility of dying from other causes. This indicator is the best estimate for comparing survival among different populations or different periods of diagnosis: differences in net survival are not attributable to the risk of dying from causes other than cancer; it is, therefore, very important from a public health perspective.*

**PLEASE NOTE.** *In the 2011 AIRTUM Report on Survival, net survival was estimated through relative survival. In the present monograph the Pohar-Perme approach was used instead. In each graph only the definition "net survival" is reported. The "crude probability of death" approach allows us to quantify the probability of dying from cancer, the probability of dying from other causes, and the probability of surviving within a defined time interval. This indicator provides actionable information for both patients and clinicians interested in the actual chances of surviving and dying.*

## IL GRAFICO DELLA SOPRAVVIVENZA NETTA CUMULATIVA STANDARDIZZATA

La sopravvivenza dipende dal tempo trascorso dalla data di diagnosi. Nella pratica ci si riferisce a una misura sintetica di questo andamento, chiamata sopravvivenza cumulativa, calcolata a una certa distanza temporale. Se, per esempio, la distanza di nostro interesse corrispondesse a 5 anni e la sopravvivenza fosse calcolata separatamente anno per anno, la sopravvivenza cumulativa sarebbe interpretabile come probabilità di sopravvivere per almeno 5 anni e, quindi, ottenuta "cumulando" (moltiplicando) le probabilità di sopravvivere il primo anno, il secondo anno, eccetera, fino al quinto anno. L'andamento della sopravvivenza cumulativa è decrescente, generalmente con una forma non dissimile da quella mostrata nel grafico. Si noti che nella pratica, così come in questo volume, quando si fa riferimento a una sopravvivenza calcolata a distanza di tempo dalla diagnosi, si intende implicitamente una sopravvivenza cumulativa, specificazione che verrà omessa.

Quando si confronta la sopravvivenza di due popolazioni diverse, è possibile che alcune differenze siano spiegate semplicemente da una differente distribuzione per età (le popolazioni più anziane tenderanno ad avere una prognosi più severa e popolazioni più giovani saranno spesso associate a sopravvivenze più elevate): per questo motivo, al fine di permettere il confronto dei risultati della presente monografia con altri studi, è presentata la sopravvivenza netta standardizzata per età, ovvero calcolata dando un peso standard (definito a priori secondo le convenzioni internazionali – vd. «Materiali e metodi», pp. 205-26) alle varie classi di età all'incidenza.

### COME SI LEGGE QUESTO GRAFICO

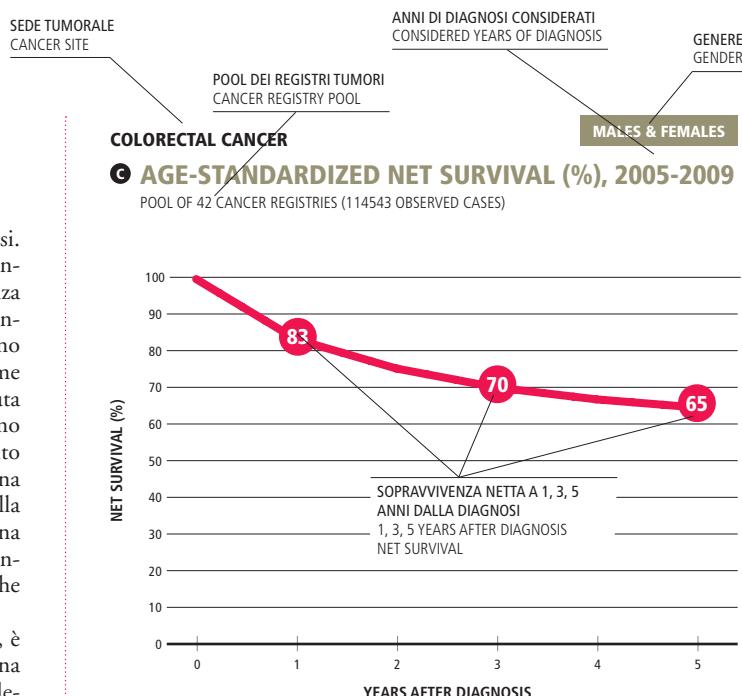

La figura mostra l'andamento della sopravvivenza netta fino a 5 anni dopo la diagnosi dei pazienti con tumore del colon retto diagnostico nel periodo 2005-2009, la fonte è il pool dei 42 Registri Tumori italiani. Nell'esempio la sopravvivenza alla fine del primo anno dalla diagnosi è pari all'83%. La sopravvivenza netta alla fine del terzo anno dopo la diagnosi è del 70% mentre, a 5 anni dalla diagnosi, è 65%.

### COME SI INTERPRETA QUESTO GRAFICO

La sopravvivenza a 5 anni è molto importante in quanto rappresenta la più comune misura sintetica usata per dare indicazioni sulla prognosi a breve termine.

In questo esempio si osserva che alla fine del primo anno l'83% dei pazienti sopravvive al tumore, ovvero si stima che il 17% dei pazienti sia deceduto per la causa tumorale in quanto eccede la mortalità osservata nella popolazione generale. Generalmente la curva tende, negli anni successivi, a diminuire la propria pendenza, segno che l'eccesso di mortalità si riduce e che la prognosi dei pazienti si avvicina sempre di più alla prognosi della popolazione.

Non sempre però l'andamento è così netto, a volte, come per i tumori della mammella, la curva non tende ad appiattirsi, segno che la malattia continua a produrre effetti sensibili anche a distanza di tempo dalla diagnosi. In seguito l'introduzione di una grandezza, chiamata sopravvivenza condizionata, aiuterà a descrivere meglio anche questi fenomeni.

### CUMULATIVE NET SURVIVAL GRAPH

*Survival depends on the time elapsed from the date of diagnosis. A summary measure of net survival is cumulative net survival, which is computed after a certain interval from diagnosis. Given a five-year distance from diagnosis and calculating survival separately each year, five-year cumulative net survival can be interpreted as the proportion of patients surviving cancer 5 years after diagnosis and can, therefore, be obtained by "cumulating" (multiplying) the survival probability for the first year, second year, and so, up to five years. The plot of cumulative net survival is similar to that shown in the figure. Note that, in practice, when referring to survival as a function of time since diagnosis, the term "cumulative" is implicit and will be omitted.*

*When comparing survival estimates among different populations, some differences may be simply due to the different age-distribution (older populations show a worse prognosis, young populations show a higher survival proportion): for this reason, in order to allow comparison of results with other studies, age-standardized net survival estimates are presented. Age-standardized estimates are calculated using a standard weight for the various age classes. Weights are a priori defined, according to International standards – see «Materials and methods», pp. 205-26).*

### HOW TO READ THIS GRAPH

*The figure shows a plot of net survival up to 5 years after diagnosis for cancer patients diagnosed with colorectal cancer in 2005-2009. The source is the pool of 42 Italian cancer registries. In this example, net survival at the end of the first year after diagnosis was 83%. Net survival at the end of the third year after diagnosis was 70%, while at 5 years after diagnosis it was 65%.*

### HOW TO INTERPRET THIS GRAPH

*Net survival after five years is very important because it is the most common single measure of short-term survival. Net survival after longer periods (mainly 10 years) is useful for measuring long-term survival and will be shown later. In this example, 83% of patients survive cancer the first year, i.e., 17% of the deaths was attributed to cancer since it exceeds the mortality of the general population. Usually, the curve tends to flatten. Sometimes, as in the case of breast cancer, there is no clear decrease in excess mortality (the survival curve does not flatten), indicating that the disease under study continues to cause deaths even long after diagnosis. Another measure, conditional survival, allows us to better describe these cases.*

## IL GRAFICO DELLA PROBABILITÀ REALE DI MORTE

La necessità di effettuare confronti nel tempo e nello spazio ha reso necessario l'utilizzo della misura precedentemente definita della sopravvivenza netta, che esprime la probabilità di sopravvivere alla patologia in studio nell'ipotetica fittizia situazione in cui le altre cause di morte non esistano. Tuttavia pazienti e clinici possono manifestare l'esigenza di acquisire informazioni relative al contesto reale, nel quale sia la patologia in studio, sia le altre comorbidità possono agire. Per tale motivo abbiamo ritenuto opportuno introdurre (per la prima volta nelle monografie AIRTUM) la stima della probabilità reale di morte (in inglese *crude probability of death*). Sono stimate congiuntamente la probabilità di morte per la patologia in studio e la probabilità di morte per altre cause (che assieme danno la probabilità di morte osservata) e anche la probabilità di non morire.

E' necessario considerare che il principale determinante della mortalità generale è l'età: essendo, quindi, il peso della mortalità generale estremamente diverso in pazienti con differenti età al momento dell'incidenza, abbiamo deciso di rappresentare la stima della probabilità reale di morte in funzione dell'età alla diagnosi.

Il riferimento temporale di 5 anni è molto importante poiché rappresenta la più comune misura sintetica usata per dare indicazioni sulla prognosi a breve termine, quindi abbiamo deciso di fornire, per questo come per altri indicatori, la sola stima a 5 anni dalla diagnosi.

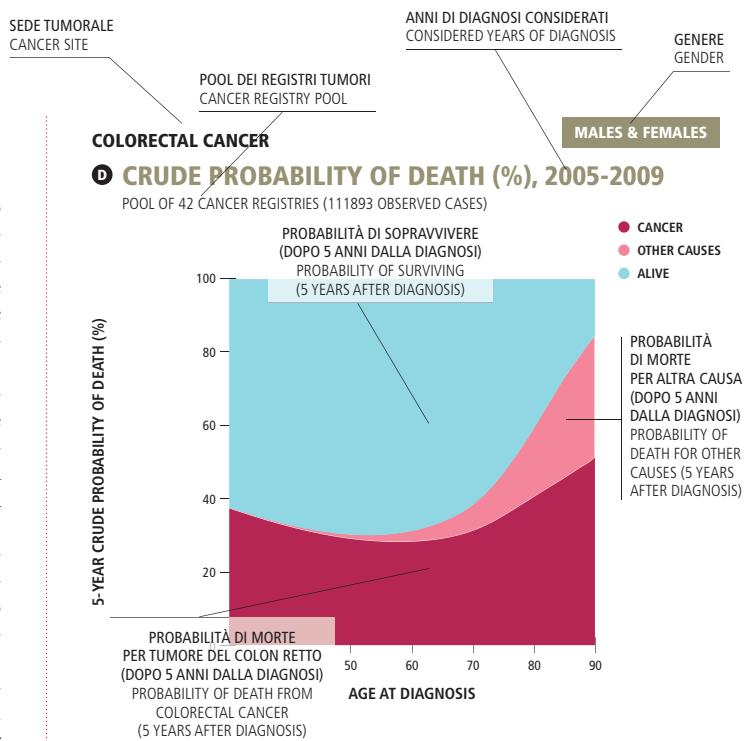

### COME SI LEGGE QUESTO GRAFICO

La figura mostra l'andamento della probabilità reale di morte per la patologia in studio, la probabilità reale di morte per altre cause e la probabilità di sopravvivere entro 5 anni dalla diagnosi di un tumore del colon retto diagnosticato nel periodo 2005-2009; la fonte è il pool dei 42 Registri Tumori italiani. Nell'esempio, per un paziente di 70 anni alla diagnosi, la probabilità reale di morte per tumore del colonretto è stata pari al 31%, la probabilità reale di morte per altre cause è stata pari al 7% nei 5 anni successivi alla diagnosi.

Per la maggioranza dei tumori indagati le stime della probabilità reale di morte si riferiscono a pazienti tra 30 e 90 anni di età alla diagnosi. Per alcuni, come il tumore della prostata, le stime riguardano età alla diagnosi comprese tra 40 e 90 anni rilevandosi pochi o nessun caso in età precedenti.

### COME SI INTERPRETA QUESTO GRAFICO

In questo grafico si osserva che probabilità reale di morte per tumore del colon retto (dopo 5 anni dalla diagnosi) è prossima al 40% per i pazienti più giovani, raggiunge valori intorno al 30% tra i sessantenni, ed è più elevata tra i pazienti più anziani.

### CRUDE PROBABILITY GRAPH

When comparing survival estimates among different populations, the net survival indicator is used. This indicator expresses the probability of surviving the specific disease, under the hypothetical assumption that other causes of death do not exist. However, patients and clinicians may be interested in the real context, where both the disease under study and other comorbidities have a role.

For this reason, estimation of the crude probability of death was included in the present report (for the first time in AIRTUM monographs). Both the probability of dying from the disease under study and the probability of dying from other causes (which together give the observed probability of death) and also the probability of surviving were estimated. The most important determinant of general mortality is age: therefore, since the weight of overall mortality is extremely different in patients with different age at diagnosis, the estimates are presented by age at diagnosis. We report only 5-year after diagnosis crude probabilities of death because it is the most common short-term prognostic indicator.

### HOW TO READ THIS GRAPH

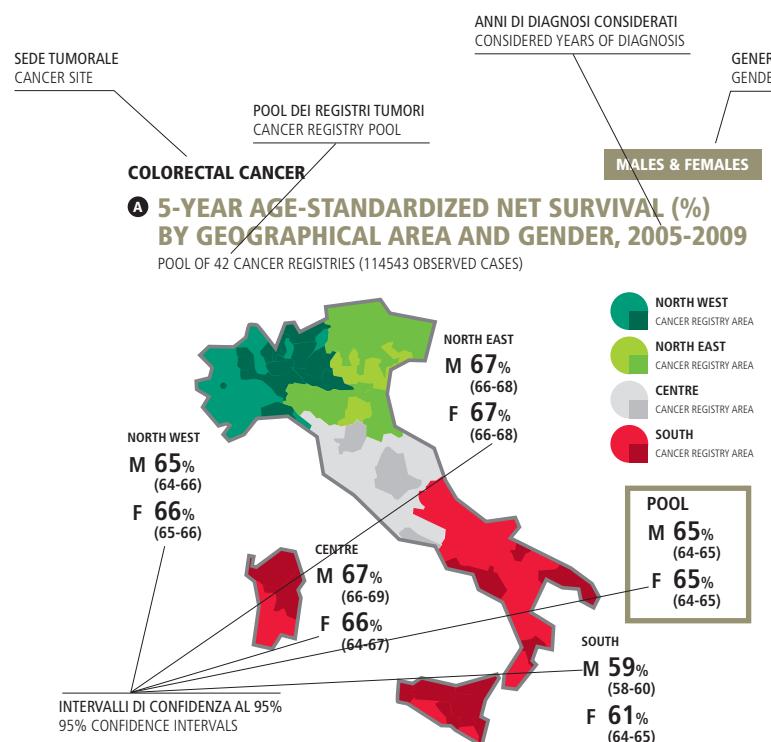

This figure shows the crude probability of dying from the disease under study, the crude probability of dying from other causes, and the probability of surviving within 5 years after diagnosis of colorectal cancer; the information source is the pool of 42 Cancer Registries (period of diagnosis: 2005-2009).

For example: a patient who is 70 years old at diagnosis has a crude probability of dying from colorectal cancer equal to 31% and a crude probability of dying from other causes equal to 7% within 5 years after diagnosis.

For almost all cancers, crude probability estimates are presented for individuals 30-90 years old at diagnosis, except for a few, e.g. prostate cancer, where estimates start from 40 years since before this age the number of cases is too small.

### HOW TO INTERPRET THIS GRAPH

In this graph, the crude probability of dying from colorectal cancer (within 5 years since diagnosis) is almost 40% among younger patients, it reaches 30% or lower among sixty-year-old patients, it is higher among older patients.

## IL GRAFICO DEI CONFRONTI NAZIONALI

In questo grafico è presentata la sopravvivenza netta standardizzata per età: quanto osservato nelle diverse aree italiane può essere comparato utilizzando questo indicatore, che presenta la probabilità di sopravvivere alla patologia in studio, al netto sia della mortalità per altre cause, sia del possibile effetto della diversa distribuzione per età della popolazione oncologica.

### COME SI LEGGE QUESTO GRAFICO

La figura mostra la sopravvivenza netta standardizzata per età a 5 anni dalla diagnosi per ripartizione geografica e per il pool dei Registri Tumori. In questo esempio la sopravvivenza a 5 anni nel Nord-Ovest è pari al 65% per gli uomini (M) e 66% per le donne (F), nel Nord-Est è 67% per entrambi i generi, nel Centro Italia è pari al 67% (M) e 66% (F) e nel Sud al 59% (M) e 61% (F). Mediamente la sopravvivenza a 5 anni riscontrata nel Pool dei Registri Tumori è stata pari al 65% (M, F). Tra parentesi è riportato l'intervallo dei valori della sopravvivenza compatibile con la variazione casuale di ciascuna stima.

### COME SI INTERPRETA QUESTO GRAFICO

Come noto, la sopravvivenza può dipendere da fattori territoriali: la qualità dell'offerta sanitaria ha un'indubbia influenza sulla sopravvivenza, includendo in essa l'efficacia delle strategie di prevenzione primaria e secondaria nonché, in generale, la qualità del percorso diagnostico-terapeutico. L'analisi della sopravvivenza per area geografica ha quindi lo scopo di fornire una indicazione, seppur sommaria, dell'impatto di questi aspetti, senza dimenticare l'influenza di altri fattori, generalmente diversi a seconda del tipo di tumore, come la prevalenza di alcuni fattori di rischio o di caratteristiche socioeconomiche.

## ITALIAN NATIONAL DISTRIBUTION GRAPH

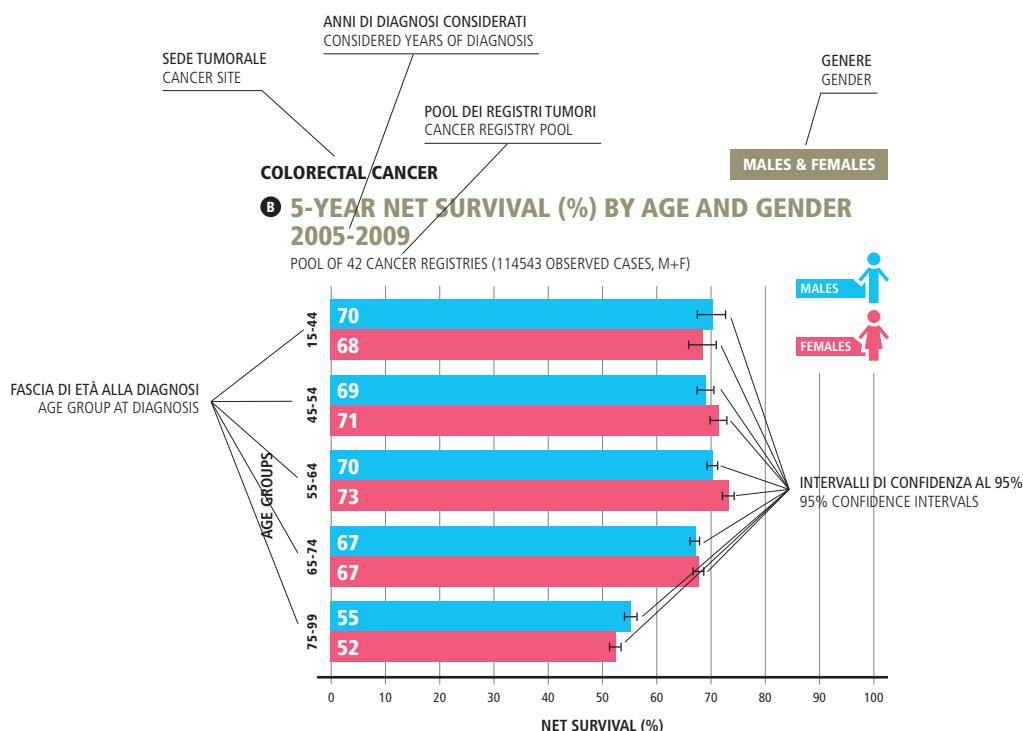

*In this graph age-standardized net survival is reported: survival in different geographic areas can be compared through this indicator that represents the probability of surviving the specific disease excluding the effect of other causes of mortality and the effect of the age distribution of cancer patients.*

### HOW TO READ THIS GRAPH

*This figure shows 5-year age-standardized net survival for the four Italian macroareas and for the pool of Italian cancer registries. In the North-West of Italy 5-year survival was 65% for males (M) and 66% for females (F), in the North-East it was 67% (M, F), in central Italy it was 67% (M) and 66% (F), and in the South it was 59% (M) and 61% (F). Overall, 5-year survival in the pool of Italian cancer registries was 65% (M, F).*

### HOW TO INTERPRET THIS GRAPH

*Survival may also depend on local factors: survival is definitely influenced by the quality of healthcare, including the efficacy of primary and secondary prevention strategies and, in general, the quality of both diagnosis and treatment. Survival analysis by geographical area is therefore useful to measure some of these aspects, as well as the influence of other cancer-specific factors, such as the prevalence of certain risk factors or socioeconomic disparities. As in the previous graph, confidence intervals (CI) are shown, expressing the uncertainty of the estimate in a range of plausible values. If the confidence intervals do not overlap (e.g., survival in the South and in the AIRTUM Pool), then estimated survival ratios are significantly different.*

## IL GRAFICO DELLA SOPRAVVIVENZA NETTA PER ETÀ

La sopravvivenza per tumore dipende dall'età: per mostrare questo effetto la sopravvivenza netta a 5 anni è quindi stata calcolata separatamente per classi di età alla diagnosi per maschi e femmine.

### COME SI LEGGE QUESTO GRAFICO

In figura è riportata la sopravvivenza netta a 5 anni dalla diagnosi dei pazienti con tumore diagnosticato nel periodo 2005-2009; la fonte è il pool dei 42 Registri Tumori italiani. Nell'esempio la sopravvivenza netta a 5 anni dalla diagnosi è stata pari al 70% per i maschi e 68% per le femmine di età compresa tra 15 e 44 anni, al 69% e 71% rispettivamente nella fascia 45-54 anni, al 70% e 73% nella fascia 55-64 anni, al 67% in entrambi i sessi nella fascia 65-74 anni e al 55% e 52% per i soggetti con età tra 75 e 99 anni.

### COME SI INTERPRETA QUESTO GRAFICO

L'effetto dell'età è spesso molto importante e la comparazione della sopravvivenza per fascia di età alla diagnosi esprime una sintesi di molti effetti che generalmente si manifestano con un incremento più o meno graduale della probabilità di morte per tumore all'aumento dell'età del paziente. Questi effetti sono legati, prima di tutto, allo stato generale del paziente e, di riflesso, alle possibilità terapeutiche. La presenza di altre condizioni morbose può ovviamente aggravare il decorso della malattia o rendere subottimale il trattamento. Molti altri aspetti influenzano l'andamento della sopravvivenza per età: le campagne di screening di popolazione, per esempio, tendono ad anticipare la diagnosi (e quindi migliorare artificialmente la sopravvivenza) in fasce di età candidate. Per esempio, nelle aree dove è attivo uno screening per i tumori della mammella e del colon retto è atteso un beneficio a favore delle fasce adulte (50-69 anni) che sarà determinato plausibilmente in parte da un artificiale aumento e in parte da un reale effetto benefico.

## NET SURVIVAL BY AGE

*Cancer survival depends on age; in order to show this, 5-year net survival was plotted by age at diagnosis.*

### HOW TO READ THIS GRAPH

*The figure shows 5-year net survival for cancer patients diagnosed in 2005-2009. The source is the pool of 42 Italian cancer registries. Five-year net survival was 70% for male patients and 68% for female patients aged between 15 and 44 years, 69% and 71% respectively for the 45-54 age group, 70% and 73% for the 55-64 age group, 67% in both sexes for the 65-74 age group and 55% and 52% respectively for patients aged between 75 and 99 years.*

### HOW TO INTERPRET THIS GRAPH

*The effect of age is often relevant. The pattern of survival by age summarizes the effect of increase in the probability of death with an increase in patient age. Differences in survival are related, first of all, to the general condition of the patient and, consequently, to treatment options. Comorbidities influence prognosis and the probability of receiving suboptimal treatment. The pattern of net survival by age is influenced by many other aspects: population screening programs, for instance, advance the time of diagnosis (therefore improving survival estimates) in the target age groups. Active breast or colorectal cancer screenings are expected to improve prognosis of participants (50-69 years).*

## IL FUNNEL PLOT DELLA SOPRAVVIVENZA REGIONALE

In conseguenza del continuo aumento delle aree coperte dai Registri Tumori in Italia, le stime della sopravvivenza netta standardizzata a 5 anni dalla diagnosi sono state presentate anche per singola regione, limitatamente alle 11 regioni italiane in cui la popolazione interessata dalla registrazione supera il 40% del totale dei residenti, oltre che per il Piemonte e la Toscana (copertura pari a 28,5% e 33,1% rispettivamente); queste ultime due regioni sono contrassegnate da un asterisco nel grafico.

### COME SI LEGGE QUESTO GRAFICO

Ogni punto del grafico rappresenta una delle 13 regioni ed è collocato in corrispondenza del livello stimato della sopravvivenza netta (asse verticale) e del livello di precisione che caratterizza la stima (asse orizzontale).

La precisione della stima, tecnicamente definita come l'inverso della varianza della sopravvivenza netta, assume valori piccoli per le regioni in cui la numerosità della popolazione interessata da registrazione nel periodo 2005-2009 è ridotta (es: Sardegna); assume valori più elevati per le regioni in cui la popolazione interessata dalla registrazione è più numerosa (es: Lombardia). La precisione dipende anche dalla letalità della malattia.

La linea nera orizzontale rappresenta la sopravvivenza netta del POOL AIRTUM.

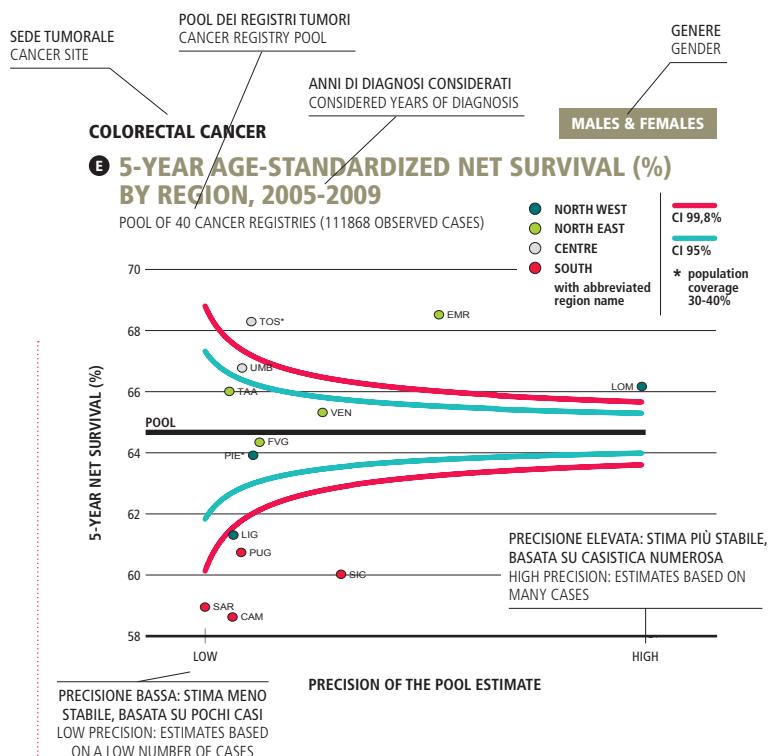

Le linee di controllo blu e rosse definiscono i limiti entro cui le stime regionali potrebbero collocarsi, sotto l'assunzione di omogeneità con la stima del POOL, discostandosi da essa per solo effetto del caso.

Le linee di controllo sono più larghe nella parte sinistra del grafico (dove si collocano regioni per le quali la stima è basata su un ridotto numero di casi e quindi è meno precisa) e più strette verso la parte destra.

La probabilità che una regione si collochi all'esterno delle linee rosse, sotto l'assunzione di omogeneità con la stima del POOL è pari allo 0,2%. La probabilità che una regione si collochi all'esterno delle linee blu è pari al 5%.

### COME SI INTERPRETA QUESTO GRAFICO

Se in tutte le regioni italiane analizzate, la sopravvivenza netta del tumore del colon retto, a 5 anni dalla diagnosi, fosse omogenea il 5% dei valori stimati potrebbe collocarsi all'esterno delle linee blu e lo 0,2% all'esterno delle linee rosse per il solo effetto del caso. In considerazione di questa probabilità molto bassa è possibile affermare che le regioni con valori esterni alle linee rosse siano caratterizzate da una sopravvivenza netta più bassa (se collocati nella parte inferiore del grafico), o eventualmente più elevata (se collocati nella parte superiore del grafico), rispetto alla media nazionale. La sopravvivenza netta riportata nel grafico è standardizzata per età. Per questo l'eterogeneità delle stime regionali non può essere attribuita alla diversa distribuzione dell'età alla diagnosi nelle casistiche delle varie regioni. Molti altri fattori, direttamente o indirettamente collegati alla sopravvivenza (vd. capitolo «Confronti internazionali», pp. 44-58), possono determinare differenze di sopravvivenza. La loro considerazione deve orientare le verifiche e stimolare la ricerca delle cause delle differenze tra le stime regionali mostrate in questi grafici.

## FUNNEL PLOT OF REGIONAL SURVIVAL ESTIMATES

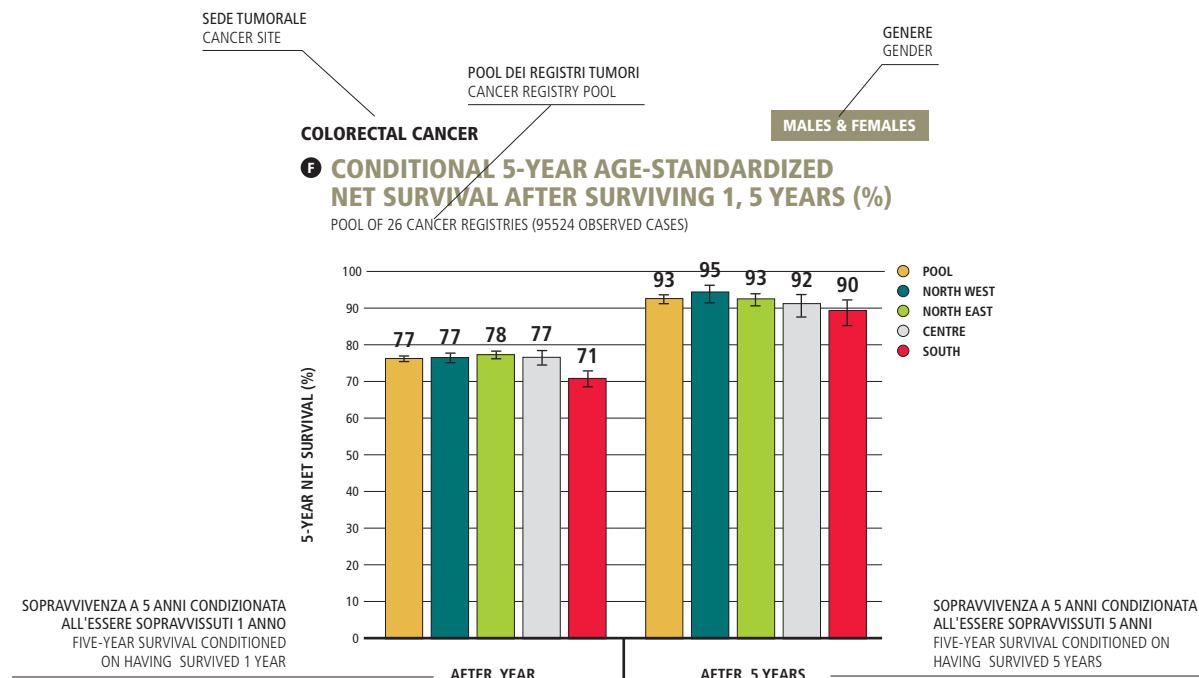

*As a result of the continuous increase in the number of areas covered by cancer registries, the 5-year age-standardized net survival estimates can be presented by region. Only 11 Italian regions with coverage higher than 40% were analysed, as well as Piedmont and Tuscany (coverage of 28.5% and 33.1%, respectively); the latter two regions are marked with an asterisk in the graph.*

### HOW TO READ THIS GRAPH

*Each point on the graph represents a region and corresponds to the net survival estimate (vertical axis) and the precision level (horizontal axis). The accuracy of the estimate, technically defined as the inverse of the variance, is smaller for regions with a small number of residents living in areas covered by cancer registries during the 2005-2009 period (e.g., Sardinia); it is higher for regions with a large number of residents living in areas covered by cancer registries (e.g., Lombardy). The accuracy also depends on the lethality of the disease. The horizontal black line represents net survival for the AIRTUM pool. The blue and red control lines define the limits within which regional estimates may be placed, under the assumption that they are homogeneous with the POOL estimate, departing from it only by chance. The control lines are wider in the left part of the graph (where the regions with a low number of cases are located) and narrower to the right. Under the assumption of homogeneity with the POOL, the probability that a region lies outside the red lines is 0.2%. The probability that a region lies outside the blue lines is 5%.*

### HOW TO INTERPRET THIS GRAPH

*If in all analysed Italian regions 5-year net survival for colorectal cancer were homogeneous, 5% of the estimated values would lie outside the blue lines and 0.2% of them would lie outside the red lines, only due to chance. As this probability is very low, we can assess that values outside the red lines identify regions with a lower net survival compared with the national average (if they are at the bottom of the graph), or with a higher survival (if they are at the top of the graph). The net survival estimates are age-standardized. For this reason, the differences between regional estimates may not be attributed to differences in the age-distribution. Many of the other factors, directly or indirectly related to survival (See the chapter «International Comparisons», pp. 44-58), can determine differences in survival.*

## GRAFICO DELLA SOPRAVVIVENZA CONDIZIONATA

La sopravvivenza condizionata esprime la probabilità di sopravvivere ulteriormente alla malattia, essendo sopravvissuto per un periodo prefissato. Nel grafico sono presentate due sopravvivenze condizionate: la sopravvivenza netta a 5 anni condizionata a essere sopravvissuto un anno dal momento della diagnosi, e la sopravvivenza netta a 5 anni condizionata ad esser sopravvissuto 5 anni. In pratica queste due misure riflettono la probabilità di sopravvivere alla malattia altri 5 anni, essendo sopravvissuto rispettivamente almeno un anno e almeno 5 anni.

### COME SI LEGGE QUESTO GRAFICO

Nell'esempio si osserva come la probabilità di sopravvivere ulteriori 5 anni per chi è sopravvissuto almeno un anno è pari al 77-78% per tutte le ripartizioni geografiche, escluso il Sud dove risulta pari al 71%. La probabilità di sopravvivere ulteriori 5 anni per chi è sopravvissuto almeno cinque anni è pari in media al 93% (barra del pool).

### COME SI INTERPRETA QUESTO GRAFICO

Come già osservato gli eccessi di mortalità dopo il primo anno tendono generalmente, ma non sempre, a contrarsi ed avvicinarsi lo zero. Ne consegue che la sopravvivenza condizionata a 5 anni dopo un anno dalla diagnosi e, soprattutto, dopo 5 anni dalla diagnosi siano più favorevoli della sopravvivenza netta calcolata al momento della diagnosi.

Il raggiungimento e il mantenimento di una sopravvivenza netta cumulata sostanzialmente invariata nel tempo indica che il gruppo dei pazienti in esame ha acquisito un rischio di decesso comparabile alla popolazione generale (che, si ricorda, è teoricamente priva del tumore). Questa condizione, se mantenuta per un ragionevole intervallo di tempo dalla diagnosi, segnala la possibile uscita di parte di alcuni pazienti dalla condizione di malattia tumorale o, in altre parole, il raggiungimento della guarigione. Usando la sopravvivenza condizionata, questa condizione potrebbe essere raggiunta, quando il valore della stessa approssimasse il 100%.

## CONDITIONAL SURVIVAL GRAPH

*Conditional survival expresses the probability of surviving for an additional amount of time once the person has survived a given amount of time. In practice, we present two types of conditional survival: conditional 5-year net survival after having survived 1 year, conditional 5-year net survival after having survived 5 years. These two measures are the probability of surviving the disease an additional 5 years after having survived at least one year and 5 years, respectively.*

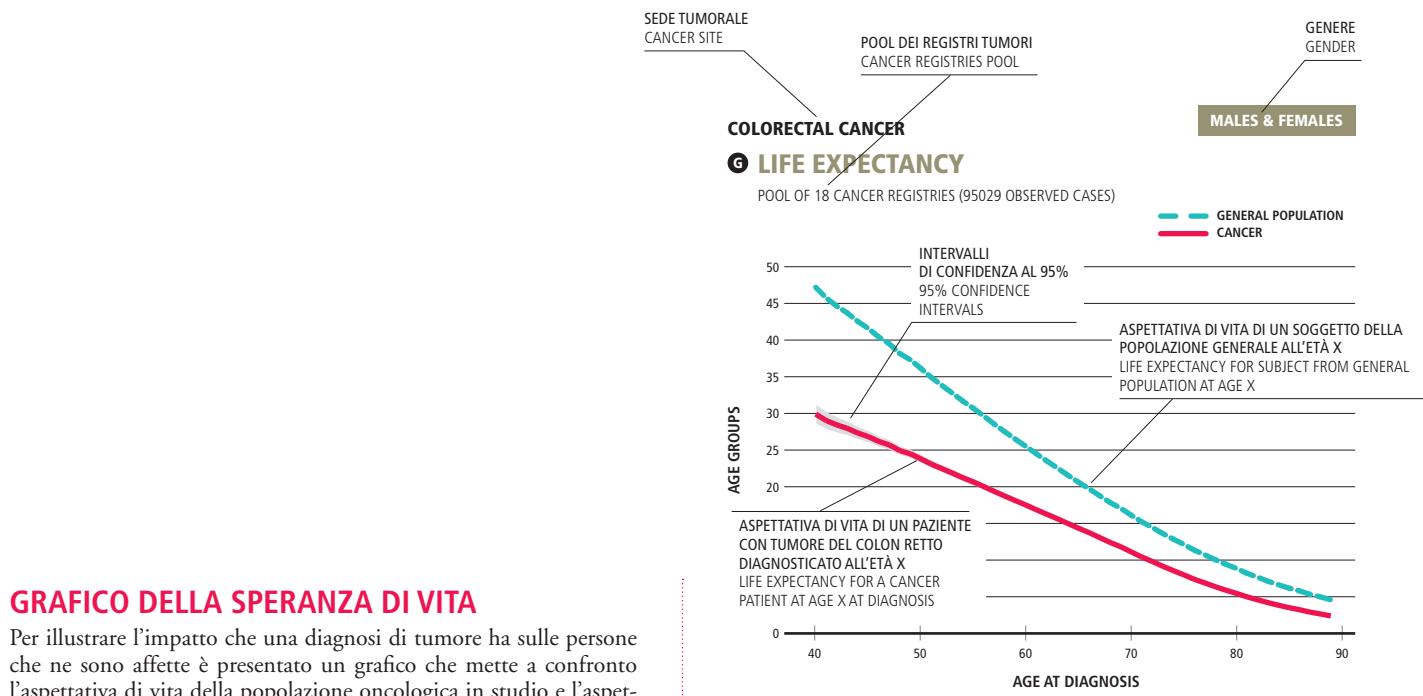

### HOW TO READ THIS GRAPH

*The figure shows that the probability of surviving an additional 5 years for patients who have already survived at least one year is 77-78% for all macroareas except the North-West, where it is 71%. The probability of surviving an additional 5 years for patients who have survived at least five years is 93% for the AIRTUM pool.*

### HOW TO INTERPRET THIS GRAPH

*As mentioned before, the excess mortality curve after the first year will generally, although not always, flatten out and approach zero. It follows that 5-year conditional survival after one year of diagnosis, and especially after 5 years of diagnosis, is higher than net survival computed from the date of diagnosis.*

*When constant cumulative net survival is reached and maintained over time, this indicates that the patient group has the same risk of death as the general population (which is theoretically free of cancer). This condition, if maintained after a reasonable number of years from diagnosis, indicates that a fraction of the patient group has escaped the disease conditions or, in other words, has been successfully cured. Using conditional survival, this condition is reached if 5-year net survival approaches 100%.*

## GRAFICO DELLA SPERANZA DI VITA

Per illustrare l'impatto che una diagnosi di tumore ha sulle persone che ne sono affette è presentato un grafico che mette a confronto l'aspettativa di vita della popolazione oncologica in studio e l'aspettativa di vita della popolazione generale utilizzata come proxy della popolazione delle persone non ammalate di tumore.

Questi dati mostrano la speranza di vita dei pazienti che oggi affrontano la diagnosi, considerato il contesto socio-assistenziale attuale. Si tratta quindi di previsioni a lungo termine. E' naturalmente possibile che un'eventuale futura introduzione di trattamenti in grado di modificare significativamente la prognosi dei tumori, anche in stadio avanzato, dia origine ad un incremento della speranza di vita stimata oggi. Per garantire la stabilità del modello utilizzato nella procedura di stima, l'indicatore riguardante la speranza di vita è presentato per i casi con 40 o più anni alla diagnosi, ad eccezione dei tumori del testicolo in cui si sono considerati i casi con 30 o più anni poiché una parte rilevante di casi interessa i giovani adulti.

Anche in questo caso, è necessario considerare che la speranza di vita è calcolata a partire dalla sopravvivenza dei pazienti oncologici e dalla mortalità della popolazione generale, entrambe fortemente correlate all'età. Per questo abbiamo ritenuto informativo rappresentare l'andamento delle stime della speranza di vita nei pazienti oncologici e nella popolazione generale in funzione dell'età.

### COME SI LEGGE IL GRAFICO

La figura mostra l'andamento della speranza di vita per la patologia in studio in funzione dell'età alla diagnosi. Nell'esempio, un individuo di 40 anni con una diagnosi di tumore del colon retto ha un'aspettativa di vita di 30 anni circa contro i 46 di una persona non affetta da tumore; se la diagnosi di questo tumore viene fatta a 70 anni l'aspettativa di vita è pari a 11 anni, mentre quella in assenza della diagnosi sarebbe stata pari a 16 anni.

### COME SI INTERPRETA IL GRAFICO

In termini assoluti la speranza di vita dei pazienti con un tumore del colon retto si riduce di 16 anni se la malattia è diagnosticata all'età di 40 anni e di 5 anni se diagnosticata a 70 anni. In termini relativi, si può osservare che mediamente per le età considerate sino a quelle più avanzate, la speranza di vita di un paziente oncologico è di circa un terzo inferiore alla speranza di vita di una persona non affetta da tumore. Questo è coerente con quanto mostrato nel grafico della sopravvivenza netta per fascia di età, nel quale si osservano sopravvivenze omogenee tra le varie classi di età, fatta eccezione per l'ultima fascia.

## LIFE EXPECTANCY GRAPH

*In this graph the life expectancy of cancer patients and the life expectancy of the general population are compared. The life expectancy of the general population is used as proxy of the life expectancy of the population with no cancer diagnosis. These data show the life expectancy of patients with a cancer diagnosis, considering the current socio-economic conditions: we are therefore dealing with long-term predictions. Life expectancy may increase if new treatments are available.*

*In order to ensure the stability of the model in the estimation procedure, the indicator is shown only for cases 40+years old at diagnosis, with the exception of testicular cancer, for which 30+ year-old patients are considered.*

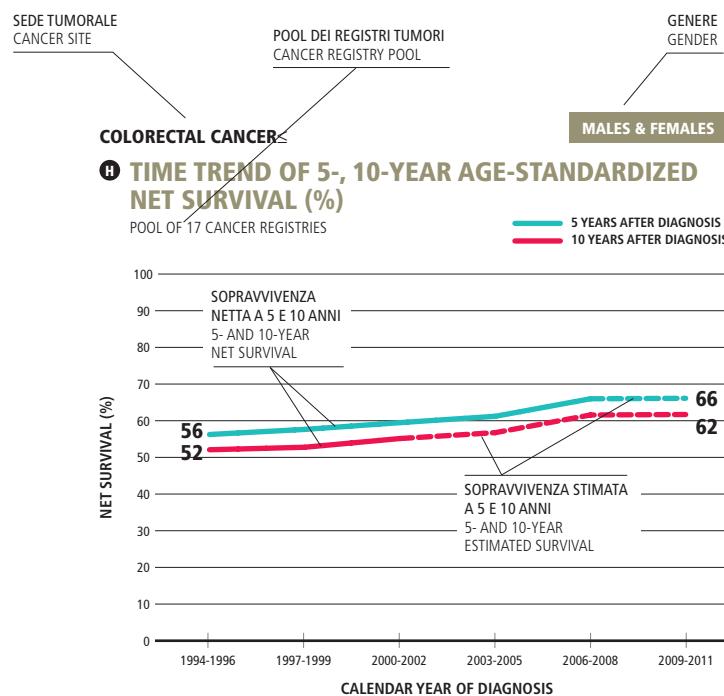

*Life expectancy is calculated on the basis of cancer patients' survival and on the basis of general population mortality, both strongly related to age. For this reason, life expectancy is presented as a function of age.*

### HOW TO READ THIS GRAPH

*This figure shows the life expectancy trend depending on age at diagnosis. In the example, a 40-year-old subject with a colorectal cancer diagnosis has a life expectancy of 30 years, compared to 46 years for people not suffering from cancer. Instead, a 70-year-old subject with a colorectal cancer diagnosis has a life expectancy of 11 years, compared to 16 years for people not suffering from cancer.*

### HOW TO INTERPRET THIS GRAPH

*In absolute terms, the life expectancy for colorectal cancer patients is lowered by 16 years if the disease occurs at the age of 40, and 5 years if it occurs at age 70. In relative terms, life expectancy remains proportionally about one-third lower than the life expectancy of a person not suffering from cancer for patients in this range of age. This is consistent with the graph of net survival by age group, where homogeneous survival estimates among the different age groups are shown (except for the older group).*

## GRAFICO DELL'ANDAMENTO DELLA SOPRAVVIVENZA NETTA

Un altro aspetto di notevole impatto sulla sopravvivenza è quello temporale, nel corso degli anni sono migliorate le tecniche diagnostiche e quelle terapeutiche e di conseguenza la sopravvivenza ne beneficia anche in modo sensibile per alcuni tumori. I dati a disposizione consentono di osservare la sopravvivenza netta a 5 e 10 anni dalla diagnosi a partire dalla metà degli anni Novanta anni per 17 Registri Tumori. Per questi Registri, con un approccio definito ibrido (vd. «Materiali e Metodi», pp. 205-26), è stato possibile proiettare le stime di sopravvivenza in periodi non ancora osservabili (per esempio, la sopravvivenza a 10 anni dei tumori diagnosticati nel 2009-2011).

### COME SI LEGGE IL GRAFICO

Nell'esempio si osserva come l'andamento della sopravvivenza netta a 5 e 10 anni dalla diagnosi sia in aumento pressoché costante. Si stima che, per i pazienti diagnosticati negli anni 2009-2011, la sopravvivenza netta sarà del 66% a 5 anni dalla diagnosi e del 62% a 10 anni dalla diagnosi.

### COME SI INTERPRETA IL GRAFICO

L'andamento della sopravvivenza indica l'impatto dell'evoluzione delle potenzialità terapeutiche e diagnostiche. Il bilanciamento tra questi due aspetti è dipendente dal tipo di neoplasia considerata; in generale, comunque, è lecito aspettarsi incrementi graduali della sopravvivenza, per le neoplasie a prognosi non severa e magari aumenti relativi importanti per le neoplasie a peggior prognosi. Esistono taluni casi in cui gli andamenti però sono fortemente condizionati dall'anticipazione diagnostica legata in particolare agli screening organizzati. Per alcuni tumori, come quelli della prostata e della tiroide, l'andamento della sopravvivenza è fortemente condizionato dall'introduzione di tecniche diagnostiche che hanno aumentato in modo drammatico l'incidenza di tumori piccoli e piccolissimi, alcuni dei quali, probabilmente, non si sarebbero mai manifestati nel corso della vita del paziente. Ovviamente questi ultimi aspetti causano difficoltà nell'interpretazione degli andamenti.

## TIME TREND OF NET SURVIVAL

*Analysis of survival time trends is important: over the past years, diagnostic and therapeutic techniques have improved and survival consequently increased for certain cancers. Five- and ten-year survival trends since the mid-90s were analysed for 17 cancer registries. Thanks to what is known as the hybrid approach (see Materials and Methods chapter, pp. 205-26) still un-observable survival was estimated (for example, 10-year survival of patients diagnosed in 2009-2011).*

### HOW TO READ THIS GRAPH

*The graph shows a steadily increasing trend for 5- and 10-year net survival. During the 2009-2011 period 5-year net survival was 66% and 10-year net survival was 62%.*

### HOW TO INTERPRET THIS GRAPH

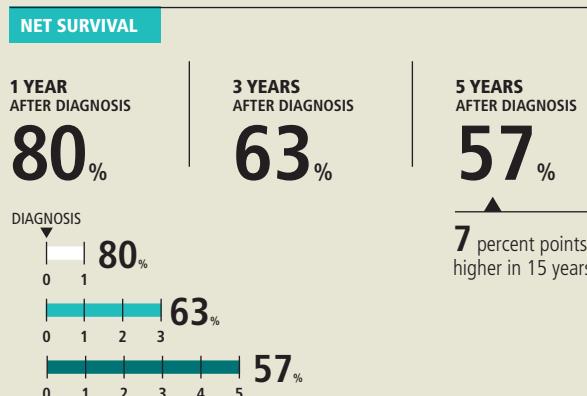

*The time trends mainly indicate the impact of improvement in diagnostic and therapeutic procedures. The weight of these two aspects depends on the cancer under study. In general, however, we expect gradual increases in survival, at least for cancer with more favourable prognosis. In some cases, the reported trends are influenced by preventive policies, such as screening programs. For some cancers, i.e., prostate and thyroid cancers, the pattern of survival is strongly biased by the introduction of diagnostic techniques that caused an increased incidence of substantially indolent cancers that are not likely to ever become symptomatic during a patient's lifetime. Obviously, these aspects make interpretation of time trends difficult.*
